

ABSTRACT OF THE DISCLOSURE

1 Samples are tested for mutations in the BRCA1 gene
2 using a hierarchical approach. First, each sample is amplified
3 in one or more multiplex PCR amplification reactions. Each
4 multiplex PCR reaction produces a mixture of amplified
5 fragments. The sizes and amounts of these fragments are
6 evaluated and compared to standard values reflecting the sizes
7 and amounts of fragments produced when the same multiplex
8 amplification is performed on the wild-type BRCA1 gene.
9 Differences between the observed fragment sizes and/or amounts
10 and those for the wild-type gene are indicative of a mutation
11 with the BRCA1 gene of the sample. Next, one or more of the
12 exons of the BRCA1 gene are sequenced, preferably only for
13 those samples where no mutation was detected by analysis of the
14 multiplex PCR fragments. The sequencing procedure can be
15 performed by amplification and sequencing of the multiplex
16 amplification mixture.
